(54) **Method for reading a graphic pattern and acquiring its image**

(57) For reading a graphic pattern compensating any illumination and/or transmission unevenness, a method is proposed, comprising the steps of:

- illuminating the graphic pattern so as to make it diffuse light;
- gathering the light diffused by the illuminated graphic pattern on a sensor having a plurality of sensitive points,
- converting, through a conversion cycle of said sensor, the light impinging the sensor point by point into electric signals representative of single points of the graphic pattern, at the same time for all sensitive

points,

characterised in that the step of illuminating the graphic pattern comprises the steps of:

- providing at least two groups of light sources, each including at least one light source operating according to an illumination cycle that comprises an illumination step and a non-illumination step,
- activating the light sources of a same group of light sources according to equal illumination cycles, the illumination cycles of light sources belonging to different groups having a reciprocally different timing.

FIG. 4

Description

[0001] The present invention relates to the reading of a graphic pattern, this term indicating a one- or two-dimensional graphic representation, such as, for example, typically an optical code (barcode, two-dimensional code, colour code, etc.), or also any image that must be acquired.

[0002] The image acquisition of a graphic pattern is typically performed according to two main techniques: the laser scanning technique, wherein the graphic pattern is scanned by a laser beam and the light diffused point by point by the illuminated graphic pattern is gathered on a substantially punctiform sensor and converted into electric signal, and the CCD or CMOS techniques, wherein more points of the graphic pattern are illuminated at the same time (on a total or partial area of the graphic pattern, or on a line) and the light diffused by all the illuminated points is gathered on a one- or two-dimensional optical sensor (of the CCD or CMOS type), capable of converting the light impinging it point by point into electric signals representing the single points of the graphic pattern, simultaneously for all sensitive points. The invention refers to the latter of the two techniques.

[0003] Theoretically, the graphic pattern can be illuminated just by the ambient light, but specific illumination means are normally used, typically sets of approximately punctiform illuminating elements (such as light diodes or LED), arranged in a one-dimensional array or in a two-dimensional matrix, according to whether the reading is made by lines or by areas.

[0004] The light diffused by the illuminated portion of graphic pattern is gathered by an optical reception system (comprising lenses, diaphragms, mirrors and the like) and focused on the optical sensor. Finally, the optical sensor comprises an array or an ordered matrix of single punctiform sensor elements, each gathering - at the same time as the others - the light coming from the graphic pattern and converting it, always at the same time as the other punctiform elements, into a set of electric signals representing the optical characteristics of the single points of the graphic pattern, thereby electrically reconstructing its image.

[0005] The problem of the unevenness of illumination on the area or line to be read is well known in the art. In fact, the central portion of the area or of the line to be read is illuminated more intensely than the peripheral zones. This phenomenon, graphically shown in figure 2 in the case of an array of four LEDs, is unavoidably associated to the geometrical arrangement of the single illuminating elements and to the fact that each of them has an emission cone of a certain width. As it can be easily seen in figure 2, the central zone receives illuminating power (light energy per area unit) from each of the various LEDs, whereas each of the two rightmost and leftmost zones only receives illuminating power from the closest LED. The resulting distribution curve of the illuminating power has a peak at about the centre

and decreases towards the ends. The same thing of course applies in case of two-dimensional illumination.

[0006] The result is that the peripheral zones of the graphic pattern are less illuminated than the central zone, and so they diffuse less light, thereby producing an image of the graphic pattern that is distorted from the luminous intensity point of view.

[0007] Moreover, the problem of the illumination unevenness is made worse by the uneven transmission of the optical reception system, which normally tends to transmit the illuminating power better in its central zone (close to the optical system axis) than in the peripheral zones. A typical pattern of this phenomenon is shown in figure 3, which shows how the power of the light composing the image decreases from the centre towards the edges.

[0008] The main effect of the phenomenon described is that the electric signal generated by the optical sensor will depend on the amount of light received, and therefore it will have a variable amplitude pattern in the field of view, according to the distance from the axis of the optical reception system.

[0009] The overlapping of this unevenness can create serious problems for the proper acquisition of the image; for example, without corrective measures it may even occur that the noise gathered in the central zone has the amplitude comparable to the signal collected in a peripheral zone. This amplitude unevenness can negatively affect the performance of the equipment for acquiring or reading the graphic pattern, in terms of reduction of the aperture or of the depth of the reading field.

[0010] Such effects are further made worse as the reading or acquisition distance increases, since the electric signal becomes weaker.

[0011] Several approaches are known in the art to correct this situation.

[0012] According to a first approach, the problem is dealt with at the origin, by providing for the central LED to be piloted so as to produce a less intense illumination compared to the peripheral ones. Examples of this approach can be found, for example, in US 4,818,847 and US 5,144,117.

[0013] According to another approach that deals with the problem at the origin as well, the spatial distribution of the LEDs and/or the orientation of their axes are not even; more precisely, the central LEDs are made to be more spaced from one another or their axes are made to diverge towards the peripheral zones. An example of this approach is provided in US 5,354,977.

[0014] Another known approach (EP-A-1205871), on the other hand, provides for an intervention during the signal electronic processing; that is, it is accepted that the generated signal is affected by the above unevenness to intervene downstream by a gain system which is variable from zone to zone of the image.

[0015] The present invention aims at providing a different approach.

[0016] Accordingly, the invention relates to a method

for reading a graphic pattern, comprising the steps of:

- illuminating the graphic pattern so as to make it diffuse light;
- gathering the light diffused by the illuminated graphic pattern on a sensor having a plurality of sensitive points,
- converting, through a conversion cycle of said sensor, the light impinging the sensor point by point into electric signals representative of single points of the graphic pattern, at the same time for all sensitive points,

characterised in that the step of illuminating the graphic pattern comprises the steps of:

- providing at least two groups of light sources, each including at least one light source operating according to an illumination cycle that comprises an illumination step and a non-illumination step,
- activating the light sources of a same group of light sources according to equal illumination cycles, the illumination cycles of light sources belonging to different groups having a reciprocally differentiated timing.

[0017] Differentiated timing means that there are time instants in which the light sources in a group are activated while the light sources in another group are not activated.

[0018] Since the method of the invention provides for the non-concurrent activation of the light sources belonging to different groups, it allows selectively illuminating the graphic pattern and therefore accounting for both illumination and transmission unevenness of the system as a whole.

[0019] Preferred solutions of the invention are indicated in the dependent claims.

[0020] Features and advantages of the present invention will appear more clearly from the following detailed description of some of its preferred embodiments, made with reference to the attached drawings. In such drawings,

- figure 1 is a diagram of an equipment for reading a graphic pattern;
- figure 2 is a diagram showing the uneven illumination if the illuminating system comprises an array of four LEDs;
- figure 3 is a diagram showing the uneven transmission of the diffused light gathered by a typical optical reception system;
- figure 4 is a diagram illustrating an embodiment of the invention, with illuminating system having two groups of light sources and optical reception system provided with shutter;
- figure 5 shows a particular case of the embodiment shown in figure 4;

- figure 6 shows four examples of readings made in different conditions, according to the embodiment shown in figure 5;
- figure 7 is a diagram similar to that of figure 4, showing another embodiment of the invention, with illuminating system having three groups of light sources and optical reception system provided with shutter;
- figure 8 is a diagram similar to that of figure 4, showing another embodiment of the invention, with illuminating system having two groups of light sources and optical reception system without shutter;
- figure 9 is a diagram similar to that of figure 4, showing another embodiment of the invention, with illuminating system having two groups of light sources and optical reception system without shutter;
- figures 10 and 11 schematically show two illuminating systems to which it is possible to apply the embodiments of the invention of figure 4, figure 5, figure 8 and figure 9;
- figure 12 schematically shows an illuminating system to which it is possible to apply the embodiment of the invention of figure 7.

[0021] Figure 1 shows a graphic pattern 1, for example a barcode, whose reading is performed by a reading equipment, only schematically shown and globally indicated with reference numeral 2, which comprises an illuminating system 3, an optical reception system 4, a sensor 5, a signal processing unit 6, and a decoding unit 7. In the operation, the single points of the graphic pattern 1 illuminated by the illuminating system 3 emit diffused light that is gathered by the optical system 4 and carried onto sensor 5, where it is converted into electric signals that are first processed in the processing unit 6, and then decoded in the decoding unit 7.

[0022] Sensor 5 consists of a plurality of flanked sensitive points, each of which generates - at the same time as the other sensitive points - an electric signal correlated to the characteristics of the light that impinges on it, and thereby to the characteristics of a corresponding point of the graphic pattern 1; the sensitive points can be arranged along a line (one-dimensional sensor), or in an area (two-dimensional sensor). Typically, said sensor 5 will be of the CCD or CMOS type.

[0023] The optical system 4 can optionally be provided with a shutter 8, for example of the mechanical type. According to an alternative preferred solution, an electronic shutter 8' can be directly associated to sensor 5. The electronic shutter 8' operates on the converted signal removing (resetting) the portion of signal converted starting from an initial instant to a subsequent predetermined instant. The action of shutter 8 or 8' can be controlled by signals generated by a control unit integrated in the same sensor, or separate from the sensor and contained in a suitable microcontroller (not shown).

[0024] The illuminating system 3 comprises a plurality of light sources 9 divided into groups. More precisely, in

the figures from 10 to 12 the illuminating system and the light sources are indicated, besides reference numerals 3 and 9, by a letter, according to the variant of the invention considered; moreover, the light sources 9 are marked by a further number to indicate the group they belong to.

[0025] So, figure 10 illustrates a one-dimensional illuminating system 3a, comprising four light sources 9a, divided into two groups according to their distance from the optical axis X of the illuminating system 3a itself; the two light sources 9a₁ closer to the optical axis X belong to the first group, while the two light sources 9a₂ farther from the optical axis X belong to the second group.

[0026] Similarly, figure 11 illustrates a two-dimensional illuminating system 3b, comprising eight light sources 9b, divided into two groups according to their distance from the optical axis Y of the illuminating system 3b itself; the four light sources 9b₁ closer to the optical axis Y belong to the first group, while the four light sources 9b₂, farther from the optical axis Y, belong to the second group.

[0027] Finally, figure 12 illustrates a one-dimensional illuminating system 3c, comprising six light sources 9c, divided into three groups according to their distance from the optical axis W of the illuminating system 3c itself; the two light sources 9c₁ closer to the optical axis W belong to the first group, the two light sources 9c₂ at an intermediate distance from the optical axis W belong to the second group, while the two sources 9c₃, farther from the optical axis W, belong to the third group.

[0028] The illuminating system may also comprise an optical emission system (not shown) containing one or more lenses and possibly diaphragms, for focusing the light emitted by the light sources 9.

[0029] The embodiment of the invention shown in figure 4 provides for the presence of shutter 8 and for the light sources 9 to be divided into two groups. With reference to said embodiment, each light source 9a and 9b is fed according to an illumination cycle 20, which comprises an illumination step 21 and a non-illumination step 22 following one another over time; the action of shutter 8 makes the conversion on sensor 5 occur according to a conversion cycle 23 (or scanning period), comprising a non-acquisition step 24 and an acquisition step 25 (or exposure time) following one another over time.

[0030] As shown in figure 4, the illumination cycle of the light sources 9a₁, 9b₁, indicated with reference numeral 20₁, is equal to the illumination cycle of the light sources 9a₂, 9b₂, indicated with reference numeral 20₂, but the two cycles are not timed. This time difference causes the light emitted by the light sources 9a₁, 9b₁ of the first group to be partly unused or rejected, since it corresponds with the non-acquisition step 24; on the other hand, the light emitted by the light sources 9a₂, 9b₂ of the second group is fully used. The non-use of part of the light emitted by the light sources 9a₁, 9b₁ of the first group therefore allows compensating both the

illumination unevenness and the transmission unevenness.

[0031] The amount of unused light emitted by sources 9a₁, 9b₁ of the first group can be adjusted both by adjusting the time difference between the two illumination cycles 20₁ and 20₂, and adjusting the period of the non-acquisition step 24, as well as adjusting the period of the illumination step 21.

[0032] A particular and interesting case is that shown in figure 5, wherein the illumination step 21 is equal to the non-illumination step 22, and the two cycles 20₁ and 20₂ are in phase opposition. The phase opposition provides for a single group of light sources always on, thereby reducing the peak current absorbed by the illuminating system 3. Figure 6 shows for this case the effect of the variation of the period of the acquisition step 25 (or exposure time) on the signal produced by sensor 5; the four curves show how such period can be advantageously adjusted to reduce, cancel or even reverse the effects of the illumination and transmission unevenness.

[0033] The embodiment of the invention shown in figure 7 provides for the presence of shutter 8 and for the light sources 9 to be divided into three groups. With reference to such embodiment, each light source 9c is fed according to an illumination cycle 30, which comprises an illumination step 31 and a non-illumination step 32 following one another over time; the action of shutter 8 makes the conversion on sensor 5 occur according to a conversion cycle 33, comprising a non-acquisition step 34 and an acquisition step 35 following one another over time.

[0034] As shown in figure 7, the illumination cycle of the light sources 9c₁, indicated with reference numeral 30₁, is equal to the illumination cycle of the light sources 9c₂, indicated with reference numeral 30₂, and to that of the light sources 9c₃, indicated with reference numeral 30₃, but the three cycles are not timed. This time difference causes the light emitted by the light sources 9c₁ of the first group and 9c₂ of the second group to be partly unused or rejected, since it corresponds with the non-acquisition step 34; on the other hand, the light emitted by the light sources 9c₃ of the third group is fully used. The non-use of part of the light emitted by the light sources 9c₁ and 9c₂ of the first and of the second group therefore allows compensating both the illumination unevenness and the transmission unevenness.

[0035] As in the case of figure 4, also in this case the amount of unused light emitted by the sources 9c₁ of the first group and 9c₂ of the second group can be adjusted both by adjusting the time difference between the illumination cycles 30₁, 30₂ and 30₃ and adjusting the period of the non-acquisition step 34, as well as adjusting the period of the illumination step 31.

[0036] The embodiment of the invention shown in figure 8 provides for no shutter and for the light sources 9 to be divided into two groups. With reference to such embodiment, each light source 9a and 9b is fed according to an illumination cycle 40, which comprises an illu-

mination step 41 and a non-illumination step 42 following one another over time; without shutter, potential acquisition (or scanning) steps follow one another on sensor 5, which are alternately rejected and used, so as to have a conversion cycle 43, which comprises a non-acquisition step 44 and an acquisition step 45, having the same period, that follow one another over time.

[0037] The situation is therefore similar to that discussed with reference to figure 4.

[0038] The embodiments illustrated in figures 4-7 exhibit illumination cycles having the same period as the conversion cycle 23 (or 33) of the sensor. According to a variant, the conversion cycle 23 has a longer period than the illumination cycles. It is possible to select only a part of such cycle corresponding to the period of the illumination cycles, thereby determining the acquisition step 25 and the non-acquisition step 24. That is, in this case the method only works on the first illumination cycle and the converted signal in the remaining portion of cycle 23 is rejected.

[0039] The embodiment of the invention shown in figure 9 provides for no shutter and for the light sources 9 to be divided into two groups. With reference to such embodiment, each light source 9a and 9b is fed according to an illumination cycle 50, which comprises an illumination step 51 and a non-illumination step 52 following one another over time. The illumination cycles 50 differ in the two groups of sources 9a and 9b and in particular, the period of the illumination step 51₂ for sources 9a₂ and 9b₂ (cycle 50₂) is longer than that 51₁ for sources 9a₁, 9b₁ (cycle 50₁). Conversion cycles 53 follow one another on sensor 5 with a period corresponding to that of the illumination cycles 50; the conversion cycles 53 only comprise an acquisition step 55 and no non-acquisition step. The effect of this solution is that the quantity of light emitted by the sources of the second group 9a₂ and 9b₂ (given by the integral of the respective waveform represented) is greater than that emitted by the first group, therefore compensating both the illumination unevenness and the transmission unevenness.

[0040] According to a variant, the conversion cycle 53 has a longer period than the illumination cycles 50₁ and 50₂. It is possible to select only a portion of such cycle corresponding to the period of the illumination cycles, thereby determining the acquisition step 55.

[0041] The embodiments shown in figures 4-8 exhibit equal illumination cycles between the different groups of sources.

[0042] However, it is also possible to differentiate such cycles from one another, for example by increasing the period of the illumination step of a given group of sources with respect to another one, similarly to what described for the embodiment of figure 9. In this way it is possible to increase the correction effect already produced by the non-use of part of the light emitted by a predetermined group of sources.

[0043] Moreover, it is possible to increase the effect given by the methods illustrated above by also differen-

tiating the intensity of the sources feeding current for the different groups of sources, for example suitably increasing it in cycles 20₂ of figures 4 and 5, 30₃ of figure 7 and 40₂ of figure 8.

5 [0044] Finally, in all of the above embodiments, it is possible to vary the intensity of the sources feeding current according to the distance of the graphic pattern.

[0045] The invention has been described in various embodiments with reference to the typical case in which the illumination and transmission unevenness occurs as shown in figures 2 and 3, with peak (or privileged illumination zone) in the proximity of the optical axis, and minimum at the periphery. However, it can be advantageously applied in all cases of unevenness occurring for any reason, wherever the privileged illumination zone; it will be sufficient to select the groups of light sources in the most appropriate manner according to the specific unevenness to compensate.

Claims

1. Method for reading a graphic pattern, comprising the steps of:

- illuminating the graphic pattern so as to make it diffuse light;
- gathering the light diffused by the illuminated graphic pattern on a sensor having a plurality of sensitive points,
- converting, through a conversion cycle of said sensor, the light impinging the sensor point by point into electric signals representative of single points of the graphic pattern, at the same time for all sensitive points, **characterised in that** the step of illuminating the graphic pattern comprises the steps of:
 - providing at least two groups of light sources, each including at least one light source operating according to an illumination cycle that comprises an illumination step and a non-illumination step,
 - activating the light sources of a same group of light sources according to equal illumination cycles, the illumination cycles of light sources belonging to different groups having a reciprocally different timing.

2. Method according to claim 1, wherein the illumination cycles of all light sources are equal to one another, and wherein the illumination cycles of the light sources of a group are not timed with respect to the illumination cycles of the light sources of a different group.

3. Method according to any one of claims 1 or 2, wherein:

- the conversion cycle comprises an acquisition step and a non-acquisition step.
4. Method according to claim 3, wherein the illumination cycle of each light source and the conversion cycle have the same period. 5
5. Method according to claim 4, wherein:
- the light sources are divided into said groups according to their distance from a privileged illumination zone; 10
 - the illumination step of the light sources of a group of light sources has a temporal overlapping period with the sensor acquisition step, where the greater the distance of the sources of such group from the privileged illumination zone, the longer such period. 15
6. Method according to claim 4, wherein in the conversion cycle the acquisition step and the non-acquisition step are regulated by a shutter, which, when activated, determines the non-acquisition step, and when not activated, determines the acquisition step. 20 25
7. Method according to claim 4, wherein the sensor operates according to a succession of scanning steps having the same period, such scanning steps being alternately used and not used, so that the scanning steps used determine the acquisition steps, whereas the scanning steps not used determine the non-acquisition steps. 30
8. Method according to claim 5, wherein the groups into which the light sources are divided are two. 35
9. Method according to claim 8, wherein the illumination step of the sources of a group temporally corresponds to the non-illumination step of the sources of the other group. 40
10. Method according to any one of the previous claims, wherein the time difference between the illumination cycles is variable. 45
